1. Background

The **encroachment of trees and shrubs** in high mountains is an increasing worldwide phenomenon, which is expected to dramatically alter the **high mountain ecosystem and its functioning**. It further indicates a starting reforestation process.

Encroachment of *Betula litwinowii* (birch) shrubs, an endemic species of the subalpine belt in the Greater Caucasus, has been observed in the Kazbegi district in the last decades.

Aims and objectives of the study:

- Analysis of the floristic composition at *B. litwinowii* stands
- Quantification of the spatial extent of *B. litwinowii* forests and the relation to topographical site conditions
- Map different *B. litwinowii* encroachment stages by means of modeling

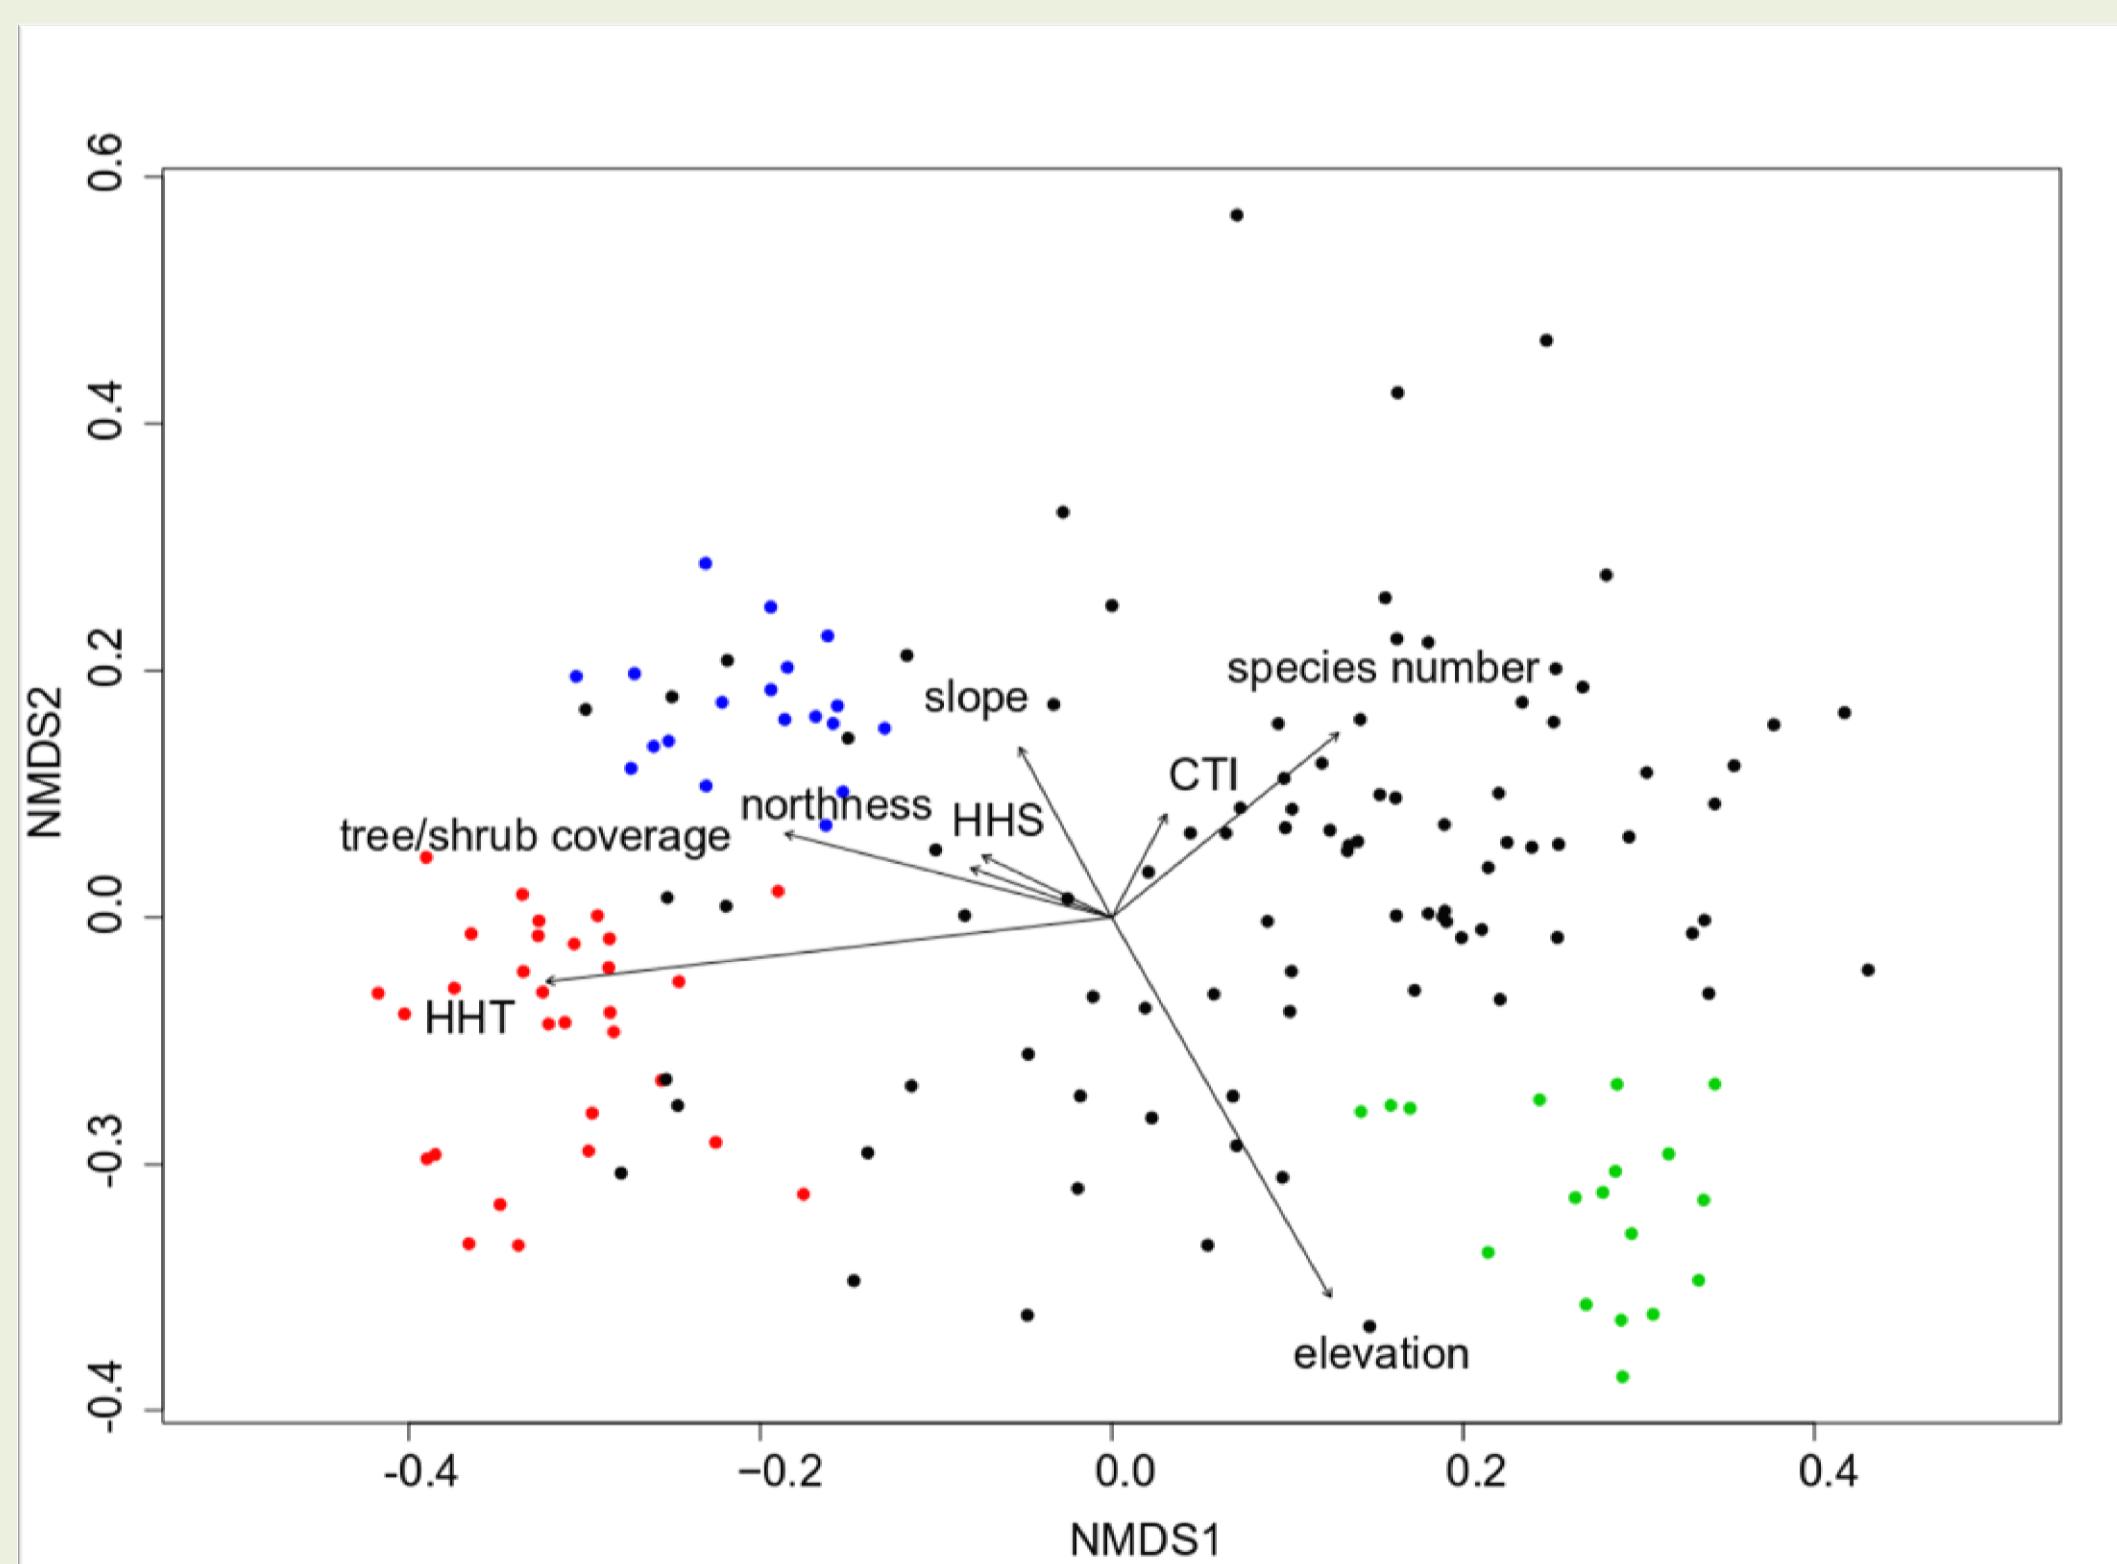

2. Methods

- Analysis of 155 vegetation relevés sampled in 2009, 2011 and 2015 to define different *B. litwinowii* vegetation groups by cluster analysis, non-metric multidimensional scaling (nmds) and an indicator species analysis.
- Assessment of *B. litwinowii* forest growth by digitizing forest outlines in aerial and space borne imagery of 1987, 2005 and 2010.
- Modeling of tree and shrub coverage using the Random Forest Algorithm as an indicator for different *B. litwinowii* encroachment stages.

3. Results

3.1 Vegetation analysis

- Four types of *B. litwinowii* stands characterized by a **gradient in tree and shrub coverage** and differing topographic positions were identified.
- Main encroachment sites: **former meadows and pastures** (initial *Bromus variegatus-B. litwinowii* encroachment), **tree line** (*Rhododendron caucasicum-B. litwinowii* tree line scrubs)

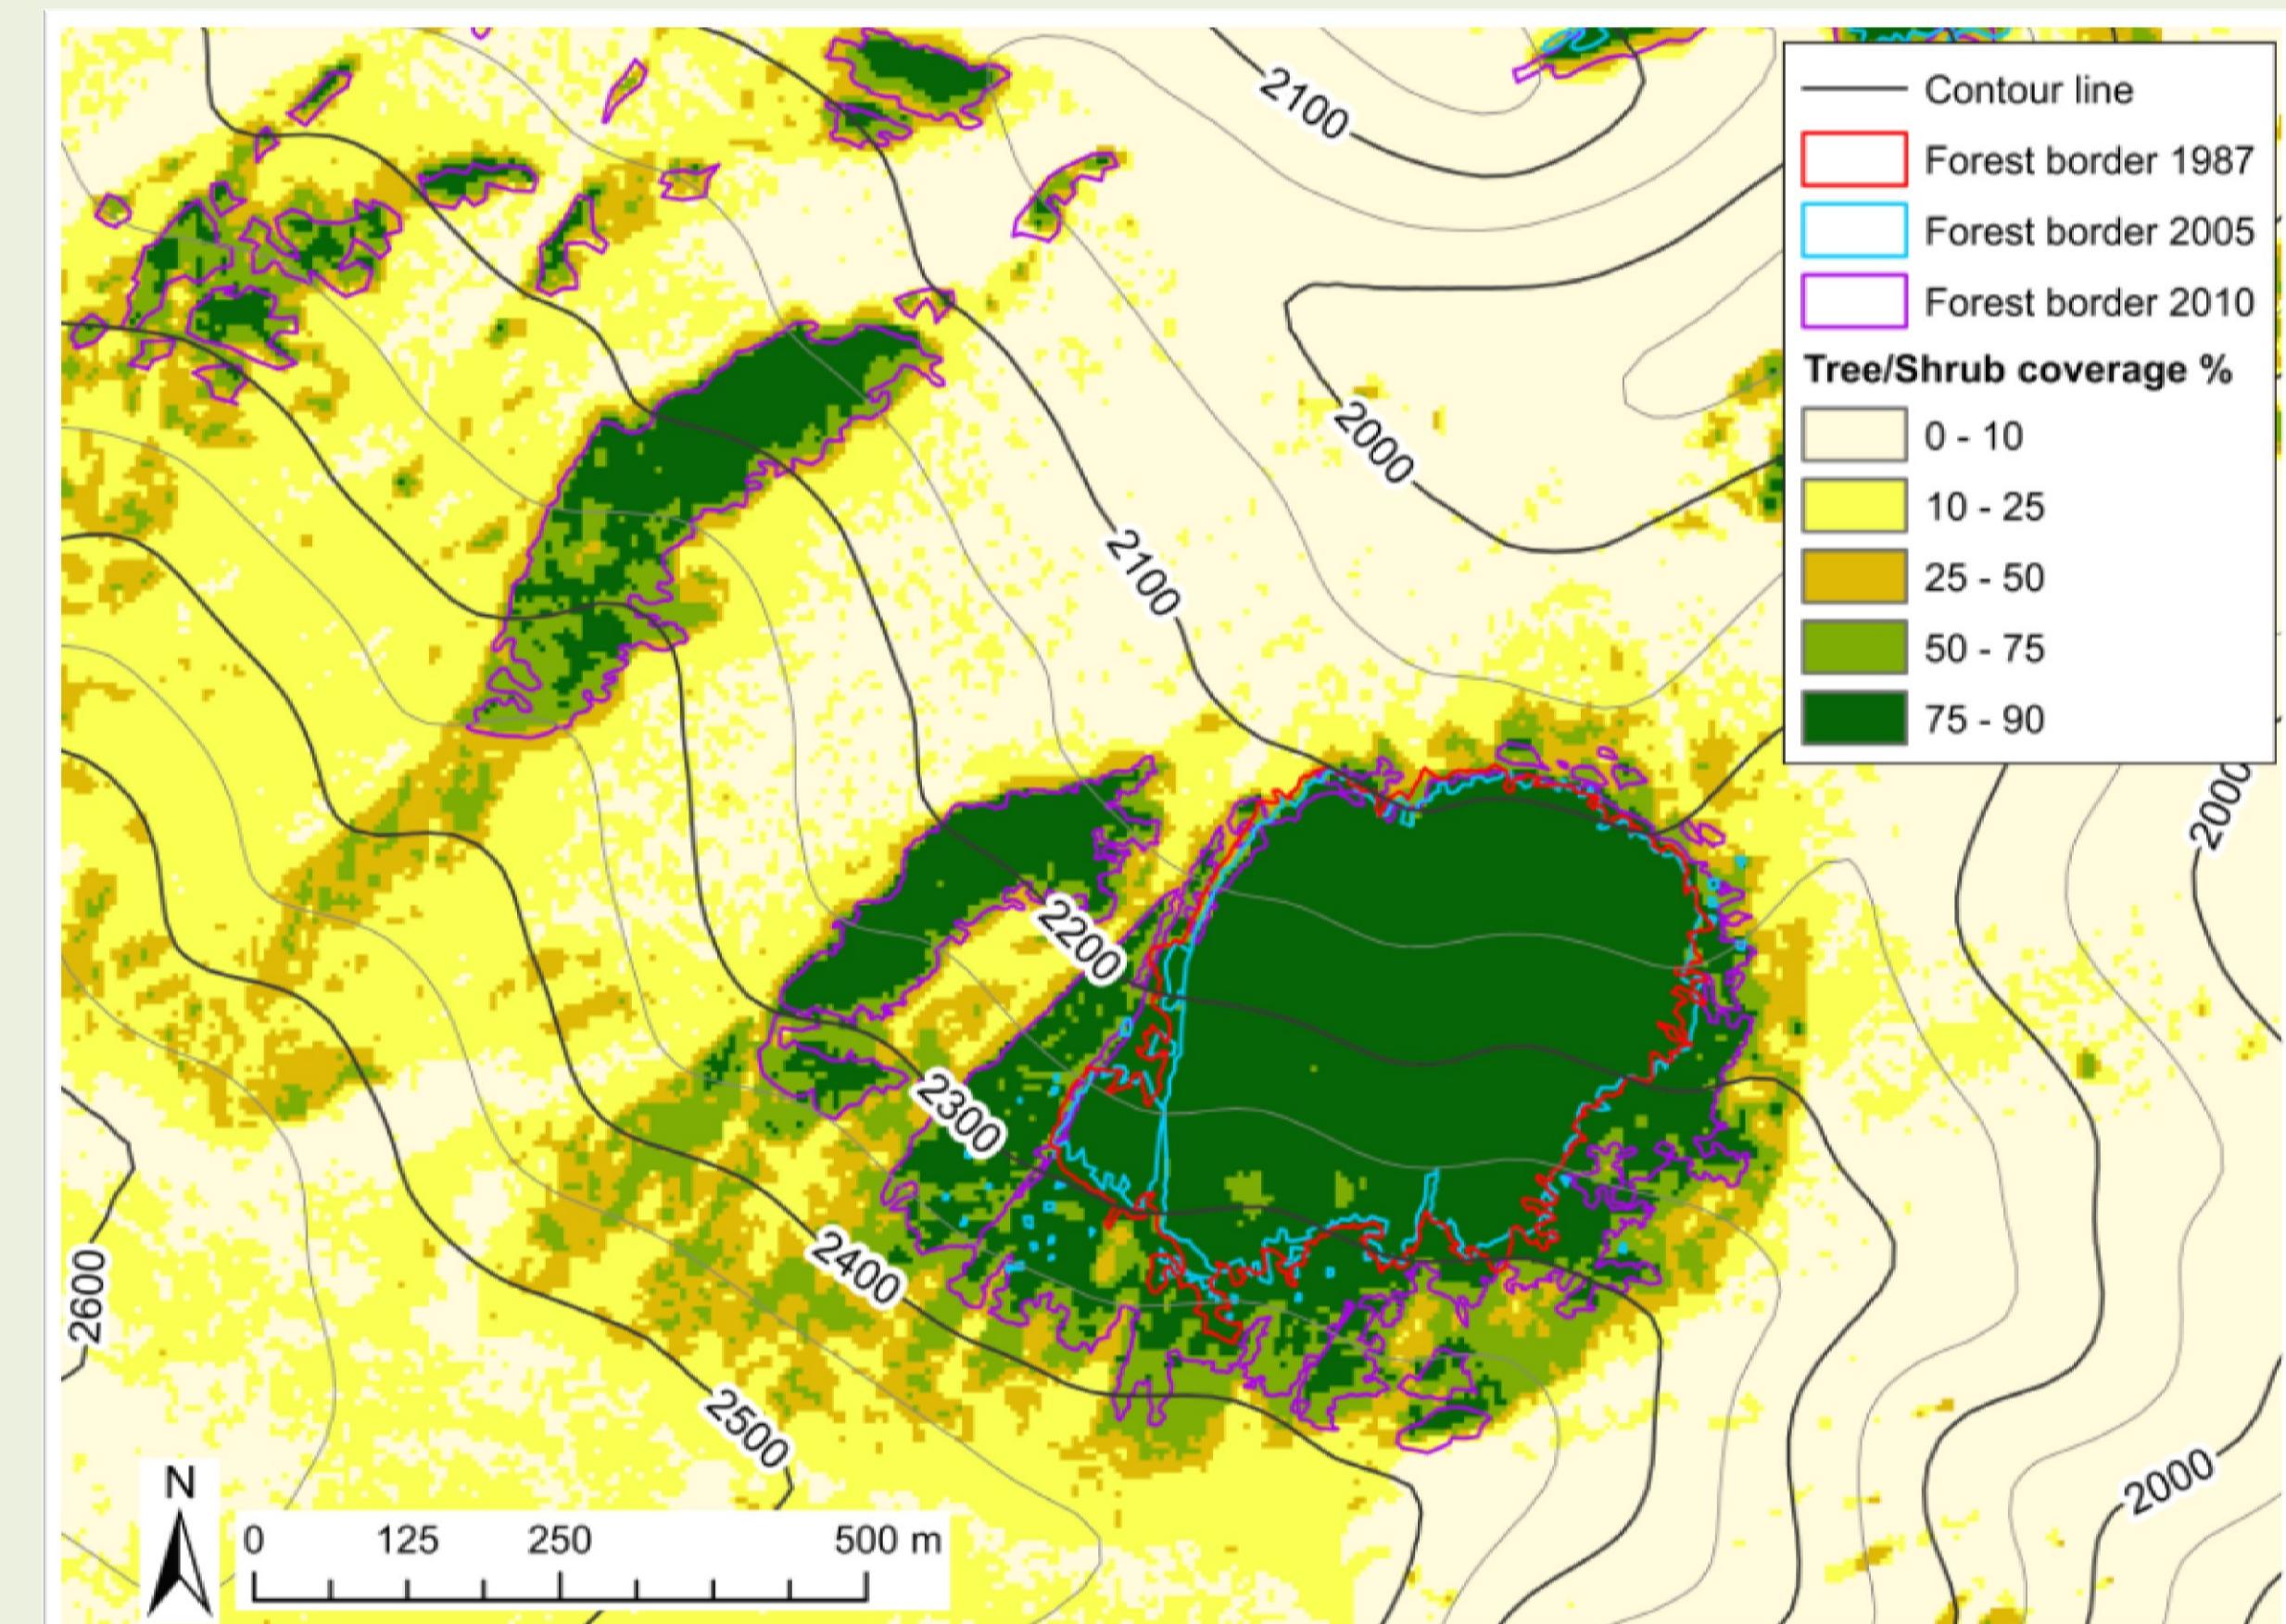

NMDS ordination of the vegetation groups: *Aconitum nasutum-B. litwinowii* forest (red), *Rubus idaeus-B. litwinowii* forest (blue), initial *Bromus variegatus-B. litwinowii* encroachment (black), *Rhododendron caucasicum-B. litwinowii* tree line scrubs (green). HHS = Height highest shrubs, HHT = Height highest trees, CTI = Compound topographic index

3.2 Forest outline digitization

- The forest increased by **25% between 1987 and 2010** mainly in uphill direction.
- Most of the area was gained between 2005 and 2010.

3.3 Modeling process

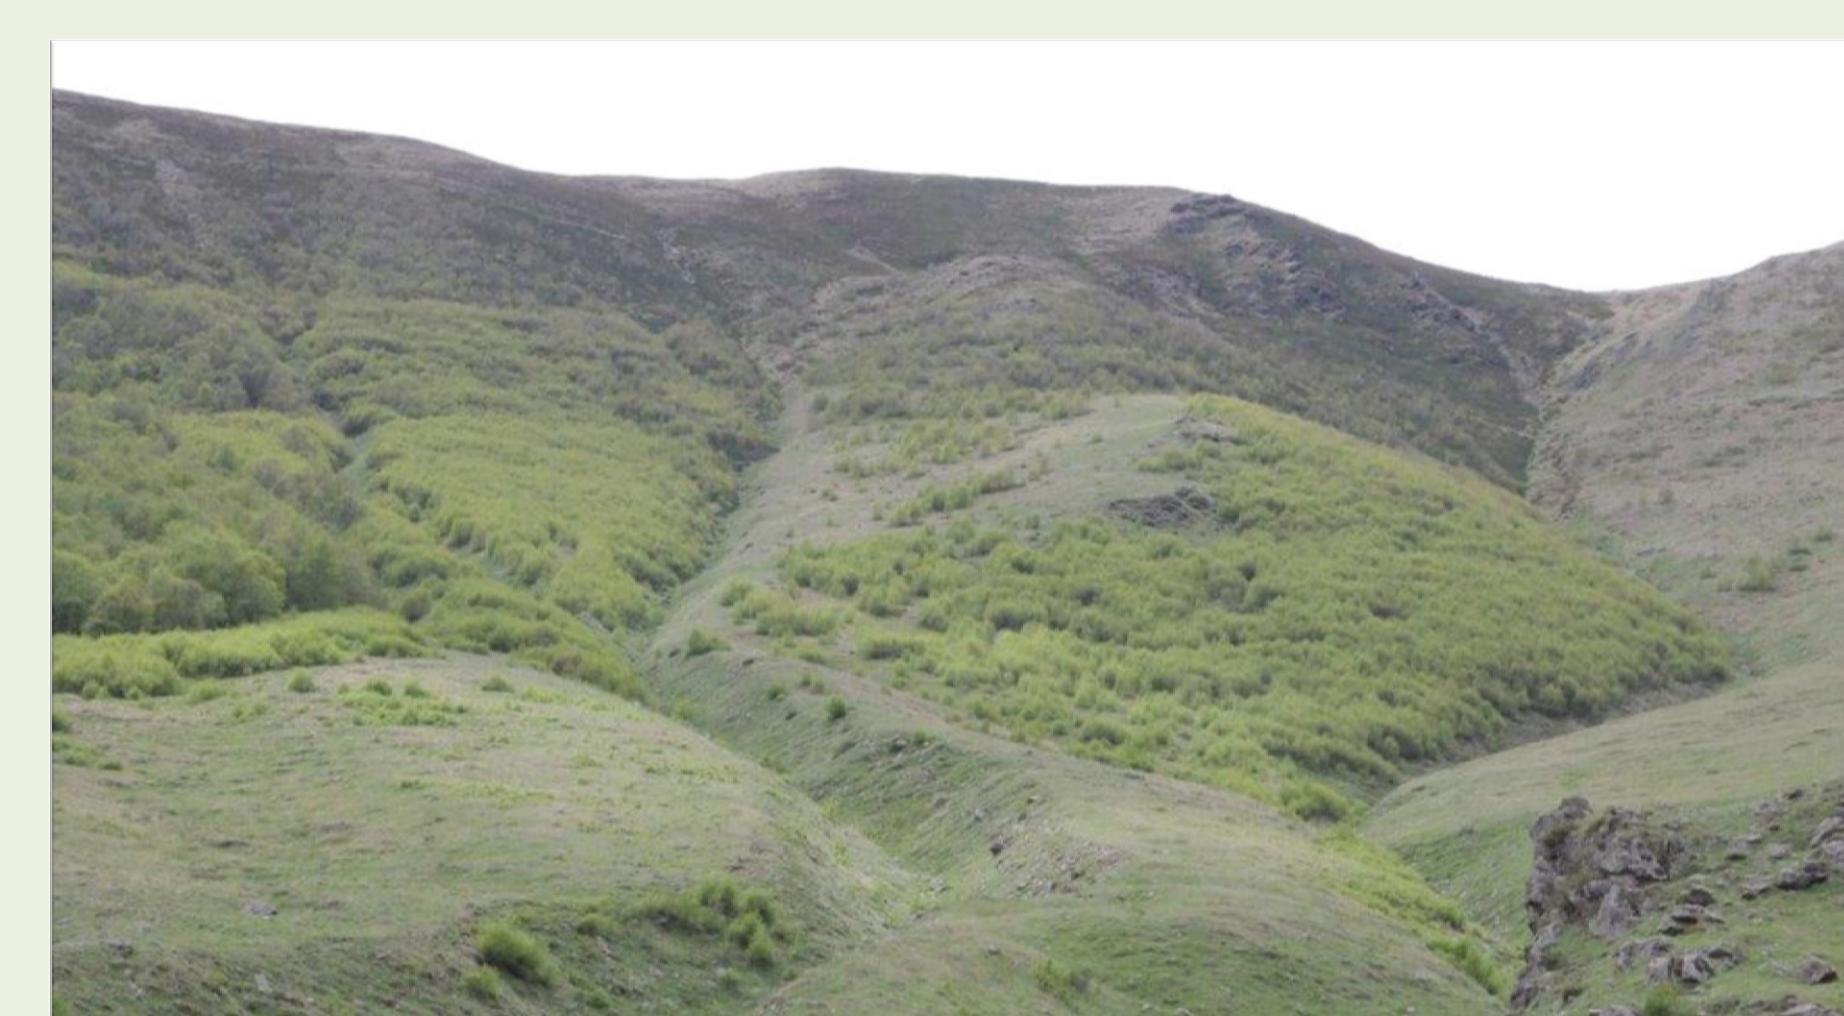

- Different encroachment stages of *B. litwinowii* could be depicted very accurately with the Random Forest algorithm ($R^2=0.69$).
- *B. litwinowii* initial succession occurs on south exposed slopes.
- Most important predictors during modeling process: the distance between the relevés and adjacent *B. litwinowii* stands as well as the red and green satellite bands.

Digitized forest outlines of 1987, 2005 and 2010 and underlying tree and shrub coverage model

4. Conclusions

- The four vegetation groups showed a relation to the modeled encroachment stages.
- A **substantial increase** in forest and shrub growth in the Kazbegi region was found, triggered by reduced grazing pressure.
- An advancement of the tree line in higher elevations was observed.
- Further encroachment of shrubs is expected to greatly **alter the high mountain ecosystem**.
- **Future studies** that monitor shrub encroachment and forest regeneration and capture the underlying drivers are needed for a **sustainable land-use management**.

B. litwinowii shrubs in the Kazbegi valley
